# Dokumentation des Paketes OPT\_OW

## 1. Einleitung

### 1.1. OPT\_OW

Dieses Paket installiert das OWFS [1.3.] und bietet so lesenden und schreibenden Zugriff auf einen an den Fli4L angeschlossenen 1-Wire-Bus. Hierzu wird z.B. ein 1-Wire Busmaster (DS 9097U-009, DS 9097U-E25 oder DS 9097U-S09 - Universal 1-Wire COM Port Adapter<sup>1</sup>) an eine serielle Schnittstelle des PC gesteckt. An die 1-Wire-seitige RJ-11 Buchse wird dann der 1-Wire Bus angelegt.

### 1.2. OW = OneWire = 1-Wire

#### 1.2.1. Der 1-Wire Standard

Der [1-Wire](#) ® bzw. One-Wire oder Eindraht-Bus von [MAXIM](#) (MAXIM hat 2001 Dallas Semiconductor übernommen, bei der die 1-Wire Technologie entwickelt wurde) beschreibt eine serielle Schnittstelle, die mit einer Datenader auskommt, die sowohl als Stromversorgung als auch als Sende- und Empfangsleitung genutzt wird. Gleichwohl ist jedoch eine „Rückleitung“ (GND) erforderlich. Jeder 1-Wire Chip hat eine unikale Identnummer über die er angesprochen wird. So können mehrere (viele) 1-Wire Geräte an einem einzelnen Bus betrieben werden.

#### 1.2.2. 1-Wire-Bauteile

MAXIM bietet eine Vielzahl von [1-Wire-Bauteilen](#) an, als da sind: Serielle-, USB-, I2C-Adapter, Thermometer, Schalter (bis 8 Kanäle), EEPROMs, Uhren, A/D-Wandler, digitale Potentiometer, u.v.a. Man bekommt eigentlich alles, was man so für die Hausautomation braucht. Eine Übersicht findet sich im Anhang unter A II.

An den Bus können auch [iButton](#) ® Bauteile (NV-RAM, EPROM, EEPROM, Temperatur, Feuchtigkeit, RTC, SHA, div. Logger) angeschlossen werden.

#### 1.2.3. 1-Wire Bus

Der 1-Wire Bus besteht im Prinzip aus zwei verdrillten Leitungen. Meist wird aber für längere Strecken (bis 150 m sollen, unter Beachtung entsprechender Topologie, kein Problem sein) normales Twisted-Pair-Ethernetkabel (Cat 5) genommen.

Zur Belegung der einzelnen Adern gibt es unterschiedliche Ansätze. MAXIM benutzt RJ-11 (6-polige) Buchsen und Stecker und hat einen eigenen Standard kreiert, der jedoch nicht zum 8-poligen RJ-45 Steckzeug passt. Hierüber gibt es aber auch einen [quasi Standard](#). Ich persönlich bevorzuge eine Weiterentwicklung<sup>2</sup>, die mit den anderen „Standards“ kompatibel ist.

---

<sup>1</sup> The DS9097U is a sophisticated RS232 to 1-Wire® adapter, which performs RS232 level conversion and actively generates the 1-Wire communication signals. Together with an adequate TMEX software driver, it enables an IBM®-compatible PC to directly communicate with any 1-Wire device connected to the adapter's RJ-11 port. The DB-9 version reads and writes any non-EPROM 1-Wire device. To write to EPROM devices, the DB-25 version with external power supply is required.

All DS9097U adapters are based on the DS2480B Serial 1-Wire Line Driver chip and therefore are not a plug-in replacement for the DS9097 or DS9097E. The RXD/TXD Polarity Select input of the DS2480B is tied to V<sub>DD</sub> (non-inverting).

<sup>2</sup> Anhang AI

Auch zum Thema [Topologie](#) des Busses wird man bei MAXIM fündig, wie überhaupt deren [Webseite](#) alles Nötige bietet, um gut mit 1-Wire zu recht zu kommen.

### 1.3. OWFS

OWFS steht für „**O**ne **W**ire **F**ile **S**ystem“. Dabei handelt es sich um eine von [Paul H. Alfilie](#) et al. entwickelte Software die unter der GPL lizenziert ist. Auf Grundlage einer 1-Wire-Protokoll verständigen Systembibliothek (OWLib) bildet OWFS den 1-Wire Bus wahlweise als Dateisystem (owfs), in Form eines tcp/ip Servers (owserver - ows-hell), oder eines http Servers (owhttpd) ab. Darüber hinaus bietet das Programm noch weitere Implementierungen (owftpd, owtap, Sprachmodule für capi, perl, tcl, php) die jedoch in der hier vorliegenden Anpassung für Fli4L nicht berücksichtigt wurden. Alles Weitere zu OWFS und viel Interessantes zu 1-Wire findet man auf: <http://owfs.org/> und <http://sourceforge.net/projects/owfs/>.

Eingesetzte Version: OWFS - 2.7p13, vom 05.01.2009.

### 1.4. Fuse

FUSE steht für „**F**ilesystem in **u**serspace“. Fuse ermöglicht die Implementierung eines voll funktionsfähigen Dateisystems im Userspace.

Da Fuse *nur* für „owfs“ benötigt wird, wird es *nur* bei dessen Installation als Kernelmodul zugeladen.

Alles weitere zu Fuse findet man auf:

<http://fuse.sourceforge.net/> und <http://sourceforge.net/projects/fuse/>.

Eingesetzte Version: Fuse - 2.7.4, vom 25.07.2008.

## 2. Lizenz

Dieses Programm ist freie Software. Sie können es unter den Bedingungen der GNU General Public License, wie von der Free Software Foundation herausgegeben, weitergeben und / oder modifizieren, entweder unter Version 2 der Lizenz oder (wenn Sie es wünschen) einer späteren Version.

Eine Kopie der GNU General Public License liegt diesem Programm bei (src/1wire/gpl.txt). Der Text der GNU General Public License ist auch im Internet unter <http://www.gnu.org/licenses/gpl.txt> veröffentlicht.

Eine inoffizielle deutsche Übersetzung findet sich unter <http://www.gnu.de/gpl-ger.html>. Diese Übersetzung soll nur zu einem besseren Verständnis der GPL verhelfen, rechtsverbindlich ist alleine die englischsprachige Version.

## 3. Gewährleistungs- und Haftungsausschluss

Die Veröffentlichung dieses Programms erfolgt mit dem Willen und der Hoffnung, dass es Ihnen von Nutzen sein wird. Dennoch wird jegliche Gewährleistung - auch die implizite Gewährleistung der Marktreife oder der Eignung für einen bestimmten Zweck - abgelehnt. Details hierzu finden Sie in der GNU General Public License (GPL).

Für Datenverlust, Schäden an Hard- oder Software oder sonstige Schäden übernimmt der Autor **keine Haftung**.

## 4. Installation

- das Paket ins Fli4I-Verzeichnis entpacken
- /config/ow.txt anpassen [6.]
- Bootmedium neu erstellen oder Remoteupdate

## 5. Kompilation, Voraussetzungen

Die Binaries und Libs wurden im fbr-3.0.0 unter Verwendung der 2.6.16.56er Kernelquellen erstellt. Für Fuse kommt das beim 2.6er Kernel mitgelieferte Modul „fuse.ko“ zum Einsatz. Das Opt wurde unter Kernel 2.4 noch nicht getestet. Sachdienliche Hinweise an den Autor erbeten.

Die mitgelieferte Fli4I-httdp Applikation basiert auf OWFS (choice 1. in /config/ow.txt). Für die Anzeige im Browser ist der Mini-Webserver (Fli4I-httdp) erforderlich. Weitere Hinweise hierzu unter 6.1.6.

## 6. Konfiguration

Die folgenden Variablen in der /config/ow.txt sind ggf. zu konfigurieren:

### 6.1. OPT\_OW

Die Standardeinstellung von *OPT\_OW='no'*, d.h. das Paket wird nicht installiert.

Mit *OPT\_OW= 'yes'* wird das Paket aktiviert.

Sie können dann unter den drei zur Verfügung stehenden Möglichkeiten wählen, in jeder beliebigen Kombination.

#### 6.1.1. owfs

Die Auswahl *ow\_owfs='yes'* erzeugt ein Dateisystem unter dem unter *ow\_owfs\_path* angegebenen Pfad. Standardeinstellung ist '/mnt/ow'. Mit der Variablen *ow\_owfs\_dev* legen Sie die Schnittstelle fest, an der der COM-zu-1wire-Adapter angeschlossen wird, /dev/ttyS0 entspricht COM1, /dev/ttyS1 entspricht COM2, usw.

Die im Dateisystem angelegten Verzeichnisse und Dateien sind nach Identnummern<sup>3</sup> der Chips geordnet. Über den family code der Bauteile ist eine entsprechende Systematik leicht herzustellen.

Mit z.B.:

- cat /mnt/ow/10.DEF0A8010800/temperature  
rufen sie die Temperaturmessung eines DS19S20 ab.
- echo "1" > /mnt/ow/1C.7F6CF7040000/PIO.O  
schaltet den Ausgang 1 eines DS28E04-100 (dual switch) ein.
- echo "0" > /mnt/ow/1C.7F6CF7040000/PIO.O  
schaltet den Ausgang 1 wieder aus.

Eine weitere Beschreibung gibt es im Anhang „A VII.“ und hier:  
<http://owfs.org/index.php?page=owfs>

---

<sup>3</sup> Anhang AII

### 6.1.2. owshell

Die OW-Shell Programme bestehen u.a. aus einem tcp-server (owserver), der standardmäßig auf Port 4304 (IANA) aktiv ist.

Die Auswahl `ow_owshell='yes'` aktiviert den owserver und installiert die Programme owdir, owread, owwrite und owget.

Die Auswahl der Schnittstelle erfolgt wie unter 6.1.1 beschrieben, default ist: `ow_owshell_dev='/dev/ttys0'`

Mit z.B.:

- `owdir`  
wird die Dateistruktur des Busses ausgelesen.
- `owread /1C.7F6CF7040000/PIO.1`  
wird der Status von Ausgang 2 des DS28E04 ausgegeben.
- `owwrite /1C.7F6CF7040000/PIO.1 1`  
wird Ausgang 2 des DS28E04 auf 1 „on“ geschaltet.

Obige Aufrufe gelten nur in Verbindung mit dem Standardport, ansonsten ist der Port explizit anzugeben (z.B. -s 4711). Sonstige Parameter und Hilfe zeigt ein „ow... -h“. Eine weitere Beschreibung gibt es im Anhang „A VII.“ und hier:

<http://owfs.org/index.php?page=owshell>

### 6.1.3. owhttpd

Der owhttpd ist ein kleiner Webserver, der den 1-Wire Bus listet.

Einstellungen analog 6.1.2.

Hier ist unter `ow_owhttpd_port='8001'` der http-Port 8001 vorgewählt. Es kann aber auch jeder andere, freie Port gewählt werden.

Mit jedem Browser kann dann mit: „Hostname:Port“ der owhttpd abgefragt werden.

Eine weitere Beschreibung gibt es im Anhang „A VII.“ und hier:

<http://owfs.org/index.php?page=owhttpd>

### 6.1.4. Rechtevergabe

- Wird, falls erforderlich, später implementiert. -

### 6.1.5. Allgemein

Wenn Sie Daten loggen wollen, können Sie das extern oder auch auf dem Fli4I tun. Im letzteren Fall benötigen Sie dann eine Festplatte bzw. Flashkarte. Näheres dazu unter OPT\_HD. Zum Sichern der Dateien sollte man OPT\_SARFILE oder OPT\_CPMVRMLOG ins Auge fassen. Die Daten lassen sich auch optisch aufbereiten, siehe OP\_RRDTOOL. Das Ganze kann man mit EASYCRON auch zeitlich automatisieren.

### 6.1.6. Bedienung im Browser

Der in Fli4I optional zu installierende httpd (Webserver) bietet die Möglichkeit, eigene Shell/CGI Skript Anwendungen über jeden Browser im Netz zu bedienen. Davon wurde im vorliegenden Falle Gebrauch gemacht.

Im OPT\_OW wird eine kleine, rudimentäre Browser Applikation mitgeliefert. Sie wird nur installiert, wenn in /config/ow.txt `OW_OWFS="yes"` gesetzt wird, da sie mit „owfs“ zusammen arbeitet. Die Anwendung kann nach eigenen Wünschen und Bedürfnissen an die zu überwachende, resp. zu steuernde Anwendung angepasst werden. Sie kann damit als Grundlage für weitere Eigenentwicklungen verwendet werden. Der

wesentliche Vorteil der Anwendung ist darin zu sehen, dass auch umfangreiche und komplexe Steuerungen unter Verwendung von Shell/CGI Skripten auf bestehender Hardware möglich sind.

Das Skript befindet sich gemäß Norm auf dem Fli4l unter /srv/www/admin/ow.cgi und im Fli4l-Installationsverzeichnis unter fli4l-version\opt\files\srv\www\admin\ow.cgi. Es kann wunschgemäß entweder mittels z.B. „WinSCP“ auf dem Fli4l selbst, oder offline z.B. im Fli4l-Installationsverzeichnis editiert werden.

(n.b.: Über die Auslagerung von 1-Wire-Device spezifischen Funktionen in eine separate Funktionsbibliothek kann zu gegebener Zeit nachgedacht werden.)

## 7. Feedback

Ich freue mich über jede, auch kurze Rückmeldung, selbst wenn das Paket ohne jegliche Probleme laufen sollte ;-).

Viel Spaß mit 1-Wire wünscht Ihr und Euer

## A VII. Man-Pages

**NAME**

**owfs** – 1-wire filesystem

**SYNOPSIS**

**owfs** *-m mountdir*

**DESCRIPTION**

**owfs**

**owfs** (1) is the filesystem client of the *OWFS* family of programs. It runs on linux, freebsd and Mac OS X, and requires the *fuse* kernel module and library. (<http://fuse.sourceforge.net>) which is a user-mode filesystem driver.

Essentially, the entire 1-wire bus is mounted to a place in your filesystem. All the 1-wire devices are accessible using standard file operations (read, write, directory listing). The system is safe, no actual files are exposed, these files are virtual. Not all operations are supported. Specifically, file creation, deletion, linking and renaming are not allowed. (You can link from outside to a **owfs** file, but not the other way around).

**SPECIFIC OPTIONS**

**-m --mountpoint=directory\_path**

Path of a directory to mount the 1-wire file system

The mountpoint is required. There is no default.

**--allow\_other**

Shorthand for fuse mount option "-o allow\_other". Allows other users to see the fuse (**owfs**) mount point and file system. Requires a setting in /etc/fuse.conf as well.

**--fuse-opt options**

Sends options to the fuse-mount process. Options should be quoted, e.g. "

**EXAMPLE**

```
owfs -d /dev/ttyS0 -m /mnt/1wire  
      Bus master on serial port
```

```
owfs -F -u -m /mnt/1wire  
      USB adapter, temperatures reported in Fahrenheit
```

```
owfs -s 10.0.1.2:4304 -m /mnt/1wire  
      Connect to an owserver (1) process that was started on another machine at tcp port 4304

**DESCRIPTION****OWSHELL programs**

**owdir** **owread** **owwrite** and **owget** are collectively called the **owshell** programs. They allow lightweight access to an **owserver** (1) for use in command line scripts.

Unlike **owserver** (1) **owhttpd** (1) **owftpd** (1) **owhttpd** (1) there is not persistent connection with the 1-wire bus, no caching and no multithreading. Instead, each program connects to a running **owserver** (1) and performs a quick set of queries.

**owserver** (1) performs the actual 1-wire connection (to physical 1-wire busses or other **owserver** programs), performs concurrency locking, caching, and error collection.

**owshell** programs are intended for use in command line scripts. An alternative approach is to mount an **owfs** (1) filesystem and perform direct file lists, reads and writes.

**owdir**

**owdir** performs a *directory* listing. With no argument, all the devices on the main 1-wire bus will be listed. Given the name of a 1-wire device, the available properties will be listed. It is the equivalent of

*ls directory*

in the **owfs** (1) filesystem.

**owread**

**owread** obtains for value of a 1-wire device property. e.g. 28.0080BE21AA00/temperature gives the DS18B20 temperature. It is the equivalent of

*cat filepath*

in the **owfs** (1) filesystem.

**owwrite**

**owwrite** performs a change of a property, changing a 1-wire device setting or writing to memory. It is the equivalent of

*echo value > filepath*

in the **owfs (1)** filesystem.

**owget**

**owget (1)** is a convenience program, combining the function of **owdir (1)** and **owread (1)** by first trying to read the argument as a directory, and if that fails as a 1-wire property.

**STANDARD OPTIONS****--autoserver**

Find an *owserver* using the Service Discovery protocol. Essentially Apple's Bonjour (aka zeroconf). Only the first *owserver* will be used, and that choice is probably arbitrary.

**-s [host:]port**

Connect via tcp (network) to an *owserver* process that is connected to a physical 1-wire bus. This allows multiple processes to share the same bus. The *owserver* process can be local or remote.

**DATA OPTIONS****--hex**

Hexidecimal mode. For reading data, each byte of character will be displayed as two characters 0-9ABCDEF. Most useful for reading memory locations. No spaces between data.

Writing data in hexidecimal mode just means that the data should be given as one long hexidecimal string.

**--start=offset**

Read or write memory locations starting at the offset byte rather than the beginning. An offset of 0 means the beginning (and is the default).

**--size=bytes**

Read up to the specified number of bytes of a memory location.

**HELP OPTIONS****-h --help**

Shows basic summary of options.

**-V --version**

*Version* of this program and related libraries.

**DISPLAY OPTIONS****-f --format f[.]i[.]c**

Display format for the 1-wire devices. Each device has a 8 byte address, consisting of:

*f* family code, 1 byte

*i* ID number, 6 bytes

*c* CRC checksum, 1 byte

Possible formats are *f.i* (default, 01.A1B2C3D4E5F6), *fi* *fic* *f.i.c* and *f.c*

All formats are accepted as input, but the output will be in the specified format.

**EXAMPLE**

**owdir -s 3000 --format fic**

Get the device listing (full 16 hex digits, no dots) from the local *owserver* at port 3000

**owread -F --autoserver 51.125499A32000/typeK/temperature**

Read temperature from the DS2751-based thermocouple on an auto-discovered *owserver* Temperature in fahrenheit.

```
owwrite -s 10.0.1.2:3001 32.000800AD23110/pages/page.1 "Passed"
```

Connect to a OWFS server process (*owserver*) that was started on another machine at tcp port 3001 and write to the memory of a DS2780

## NAME

**owserver** – Backend server (daemon) for 1-wire control

## SYNOPSIS

**owserver** *-p* *tcp-port*

## DESCRIPTION

### **owserver**

**owserver (1)** is the backend component of the OWFS 1-wire bus control system. **owserver (1)** arbitrates access to the bus from multiple client processes. The physical bus is usually connected to a serial or USB port, and other processes connect to **owserver (1)** over network sockets (tcp port). Communication can be local or over a network. Secure tunneling can be implemented using standard techniques.

Frontend clients include a filesystem representation: **owfs (1)**, and a webserver: **owhttpd (1)**. Direct language bindings are also available, e.g: **owperl (3)**. Several instances of each client can be initiated.

Each client can also connect directly to the physical bus, skipping **owserver (1)** but only one client can connect to the physical bus safely. Simultaneous access is prevented by the operating system for USB ports, but unfortunately not serial ports. The safe way to share access to the 1-wire bus is via **owserver (1)** with the clients connecting. Note: **owserver (1)** can connect to another **owserver (1)** process, though the utility of this technique is limited (perhaps as a *readonly* buffer?)

**owserver (1)** is by default multithreaded. Optional data caching is in the server, not clients, so all the clients gain efficiency.

## SPECIFIC OPTIONS

### **-p**

TCP port or IPaddress:port for *owserver*

Other OWFS programs will access *owserver* via this address. (e.g. *owfs -s IP:port /1wire*)

If no port is specified, the default well-known port (4304 -- assigned by the IANA) will be used.

## DEVELOPER OPTIONS

### **--no\_dirall**

Reject DIRALL messages (requests directory as a single message), forcing client to use older DIR method (each element is an individual message)

### **--no\_get**

Reject GET messages (lets *owserver* determine if READ or DIRALL is appropriate). Client will fall back to older methods.

### **--no\_persistence**

Reject persistence in requests. All transactions will have to be new connections.

### **--pingcrazy**

Interject many "keep-alive" (PING) responses. Usually PING responses are only sent when processing is taking a long time to inform client that *owserver* is still there.

## EXAMPLE

**owserver -p 3001 -d /dev/ttyS0** runs *owserver* on tcp port 3001 and connects to a physical 1-wire bus on a serial port.

**owhttpd -p** tcp-port

**DESCRIPTION****owhttpd**

**owhttpd (1)** is a small webserver that shows the Dallas/Maxim 1-Wire bus attached to a serial port. The main view shows the devices found, You can then navigate to individual devices, and view/alter their properties.

**owhttpd (1)** uses the same naming convention as **owfs (1)**, where the URL corresponds to the filename.

The web server is a modified version of chttpd by Greg Olszewski. It serves no files from the disk, only virtual files from the 1-wire bus. Security should therefore be good. Only the 1-wire bus is at risk.

**SPECIFIC OPTIONS****-p portnum**

Sets the tcp port the web server runs on. Access with the URL `http://servernameoripaddress:portnum`

If no port is specified, an ephemeral port is selected by the operating system. Use *zeroconf (Bonjour)* to discover the assigned port.

**EXAMPLE**

`owhttpd -p 3001 -d /dev/ttyS0`

Web server runs on tcp port 3001, serial adapter at ttyS0

`owhttpd -p 3001 -s littlehost:4304 --error_level=3`

Web server on port 3001, from *owserver* process on host "littlehost", extensive error messages.

`owhttpd -p 3001 -u -u2 -r`

Read-only web server on port 3001, using two usb adapters.

**DESCRIPTION****Configuration**

**owfs.conf (5)** allows a uniform set of command line parameters to be set.

Not all OWFS programs use the same command line options, but the non-relevant ones will be ignored.

Command line and configuration options can be mixed. They will be invoked in the order presented. Left to right for the command line. Top to bottom for the configuration file.

Configuration files can call other configuration files. There is an arbitrary depth of 5 levels to prevent infinite loops. More than one configuration file can be specified.

**FAMILY CODE**

**12**

**SPECIAL PROPERTIES****channels**

*read-only, unsigned integer*

Is this a 1 or 2 channel switch? The *DS2406* comes in two forms, one has only one *PIO* pin (*PIO.A*). Returns 1 or 2.

**latch.A latch.B latch.ALL latch.BYTE**

*read-write, yes-no*

The activity latch is set to 1 with the first negative or positive edge detected on the associated *PIO* channel. Writing any data will clear latch for all (both) channels. This is a hardware "feature" of the chip.

*ALL* references both channels simultaneously, comma separated

*BYTE* references both channels simultaneously as a single byte, with channel A in bit 0.

**memory**

*read-write, binary*

128 bytes of non-volatile, write-once data.

**pages/page.0 ... pages/page.3 pages/page.ALL**

*read-write, binary*

Memory organized as 4 pages or 32 bytes. Memory is write-once.

*ALL* is the aggregate of all 4 pages, sequentially accessed.

**PIO.A PIO.B PIO.ALL PIO.BYTE**

*read-write, yes-no*

State of the open-drain output ( *PIO* ) pin. 0 = non-conducting (off), 1 = conducting (on).

Writing zero will turn off the switch, non-zero will turn on the switch. Reading the *PIO* state will return the switch setting. To determine the actual logic level at the switch, refer to the *sensed* property.

*ALL* references both channels simultaneously, comma separated

*BYTE* references both channels simultaneously as a single byte, with channel A in bit 0.

**power**

*read-only, yes-no*

Is the *DS2406* powered parasitically =0 or separately on the *Vcc* pin =1

**sensed.A sensed.B sensed.ALL sensed.BYTE**

*read-only, yes-no*

Logic level at the *PIO* pin. 0 = ground. 1 = high (~2.4V - 5V). Really makes sense only if the *PIO* state is set to zero (off), else will read zero.

*ALL* references both channels simultaneously, comma separated

*BYTE* references both channels simultaneously as a single byte, with channel A in bit 0.

**set\_alarm**

*read-write, unsigned integer (0-331)*

A number consisting of three digits XYZ, where:

X channel selection

0 neither

1 A only

2 B only

	3 A or B
Y	source selection
	0 undefined
	1 latch
	2 PIO
	3 sensed
Z	polarity selection
	0 low
	1 high

All digits will be truncated to the 0-3 (or 0-1) range. Leading zeroes are optional (and may be problematic for some shells).

Example:

- 311      Responds on Conditional Search when either latch.A or latch.B (or both) are set to 1.
- <100     Never responds to Conditional Search.

#### TAI8570/

*subcategory*

Properties when the *DS2406 (3)* is built into a *TAI8570*.

If the *DS2406 (3)* is not part of a *TAI8570* or is not the controlling switch, attempts to read will result in an error.

#### TAI8570/pressure

*read-only, floating point*

Barometric pressure in millibar.

#### TAI8570/sibling

*read-only, ascii*

Hex address of the *DS2406 (3)* paired with this chip in a *TAI8570*.

#### TAI8570/temperature

*read-only, floating-point*

Ambient temperature measured by the *TAI8570* in prevailing temperature units (Centigrade is the default).

#### T8A/volt.[0-7|ALL]

*read-only, floating-point*

Uses the T8A (by *Embedded Data Systems*) 8 channel voltage convertor. Units in volts, 0 to 5V range. 12 bit resolution.

## STANDARD PROPERTIES

### ALARMS

Use the *set\_alarm* property to set the alarm triggering criteria.

## DESCRIPTION

### DS2406

The **DS2406 (3)** allows control of other devices, like LEDs and relays. It superceeds the **DS2405** and **DS2407**. Alternative switches include the **DS2408** or even **DS2450**.

The **DS2407** is practically identical to the **DS2406** except for a strange *hidden* mode. It is supported just like the **DS2406**.

### TAI8570

The *TAI-8570 Pressure Sensor* is based on a 1-wire composite device by *AAG Electronica*. The *TAI8570* uses 2 *DS2406 (3)* chips, paired as a reader and writer to synthesize 3-wire communication. Only 1 of the *DS2406 (3)* will allow *temperature* or *pressure* readings. Its mate's address can be shown as *sibling*.

The *TAI8570* uses the *Intersema MS5534a* pressure sensor, and stores calibration and temperature compensation values internally.

Design and code examples are available from *AAG Electronica* <http://aag.com.mx>, specific permission to

use code in a GPL product was given by Mr. Aitor Arrieta of AAG and Dr. Simon Melhuish of OWW.

Like *LCD\_H/screen* but starting at a particular screen position.

2 binary bytes

The two first characters of the passed string have the line and row: e.g. "\x02\x04string" perl string writes "string" at line 2 column 4.

ascii 2,12:

Two numbers giving line and row: Separate with a comma and end with a colon e.g. "2,4:string" writes "string" at line 2 column 4.

ascii 12:

Single column number on the (default) first line: End with a colon e.g. "12:string" writes "string" at line 1 column 12.

The positions are 1-based (i.e. the first position is 1,1).

### **LCD\_H/onoff**

*write-only, unsigned*

- 4      Display on
- 2      Cursor on
- 1      Cursor blinking

### **LCD\_H/message LCD\_M/message**

*write-only, ascii text*

Writes to an LCD screen controlled by a DS2408 using published designs.

*message* combines the actions of *clear*, *home* and *screen* so is the easiest way to display a message.

*LCD\_H* uses the Hobby-Boards design of Erik Vickery (see *DATASHEET* )

*LCD\_M* uses the Maxim public domain design (see *DATASHEET* )

### **PIO.0 ... PIO.7 PIO.ALL PIO.BYTE**

*read-write, yes-no*

State of the open-drain output ( *PIO* ) pin. 0 = non-conducting (off), 1 = conducting (on).

Writing zero will turn off the switch, non-zero will turn on the switch. Reading the *PIO* state will return the switch setting. To determine the actual logic level at the switch, refer to the *sensed.0 ... sensed.7 sensed.ALL sensed.BYTE* property.

*ALL* references all channels simultaneously, comma separated.

*BYTE* references all channels simultaneously as a single byte. Channel 0 is bit 0.

### **power**

*read-only, yes-no*

Is the DS2408 powered parasitically (0) or separately on the Vcc pin (1)?

### **sensed.0 ... sensed.7 sensed.ALL**

*read-only, yes-no*

Logic level at the *PIO* pin. 0 = ground. 1 = high (~2.4V - 5V). Really makes sense only if the *PIO* state is set to zero (off), else will read zero.

*ALL* references all channels simultaneously, comma separated.

*BYTE* references all channels simultaneously as a single byte. Channel 0 is bit 0.

### **strobe**

*read-write, yes-no*

RSTZ Pin Mode Control. Configures RSTZ as either RST input or STRB output:

- 0      configured as RST input (default)
- 1      configured as STRB output

### **por**

*read-write, yes-no*

Specifies whether the device has performed power-on reset. This bit can only be cleared to 0 under software control. As long as this bit is 1 the device will always respond to a conditional search.

### **set\_alarm**

*read-write, integer unsigned (0-333333333)*

A number consisting of 9 digits XYXXXXXXX, where:

- X      select source and logical term
- 0 PIO OR
- 1 latch OR
- 2 PIO AND
- 3 latch AND

Y select channel and polarity  
0 Unselected (LOW)  
1 Unselected (HIGH)  
2 Selected LOW  
3 Selected HIGH

All digits will be truncated to the 0-3 range. Leading zeroes are optional. Low-order digit is channel 0.

Example:

100000033

Responds on Conditional Search when latch.1 or latch.0 are set to 1.

222000000

Responds on Conditional Search when sensed.7 and sensed.6 are set to 0.

000000000 (0)

Never responds to Conditional Search.

## STANDARD PROPERTIES

**SPECIAL PROPERTIES****alarm/high.A ... alarm/high.D alarm.high.ALL****alarm/high.A ... alarm/high.D alarm.high.ALL***read-write, binary*

The alarm state of the voltage channel. The alarm state is set one of two ways:

voltage conversion

Whenever the *DS2450* measures a voltage on a channel, that voltage is compared to the high and low limits *set\_alarm/volthigh* and/or *set\_alarm/voltlow* and if the alarm is enabled *set\_alarm/high* and/or *set\_alarm/low* the corresponding flag is set in *alarm/high* and/or *alarm/low*

manual set

The flag can be set by a direct write to *alarm/high* or *alarm/low***memory***read-write, binary*

32 bytes of data. Much has special implications. See the datasheet.

**pages/page.0 ... pages/page.3 pages/page.ALL***read-write, binary*

Memory is split into 4 pages of 8 bytes each. Mostly for reading and setting device properties. See the datasheet for details.

*ALL* is an aggregate of the pages. Each page is accessed sequentially.**PIO.A ... PIO.D PIO.ALL***read-write, yes-no*

Pins used for digital control. 1 turns the switch on (conducting). 0 turns the switch off (non-conducting).

Control is specifically enabled. Reading *volt* will turn off this control.*ALL* is an aggregate of the voltages. Readings are made separately.**power***read-write, yes-no*Is the *DS2450* externally powered? (As opposed to parasitically powered from the data line).

The analog A/D will be kept on continuously. And the bus will be released during a conversion allowing other devices to communicate.

Set true (1) only if Vcc powered (not parasitically powered). Unfortunately, the *DS2450* cannot sense it's powered state. This flag must be explicitly written, and thus is a potential source of error if incorrectly set.It is always safe to leave *power* set to the default 0 (off) state.**set\_alarm/high.A ... set\_alarm/high.D set\_alarm/high.ALL****set\_alarm/low.A ... set\_alarm/low.D set\_alarm/low.ALL***read-write, yes-no*

Enabled status of the voltage threshold. 1 is on. 0 is off.

**set\_alarm/volthigh.A ... set\_alarm/volthigh.D set\_alarm/volthigh.ALL**  
**set\_alarm/volt2high.A ... set\_alarm/volt2high.D set\_alarm/volt2high.ALL**  
**set\_alarm/voltlow.A ... set\_alarm/voltlow.D set\_alarm/voltlow.ALL**  
**set\_alarm/volt2low.A ... set\_alarm/volt2low.D set\_alarm/volt2low.ALL**

*read-write, floating point*

The upper or lower limit for the voltage measured before triggering an alarm.

Note that the alarm must be enabled *alarm/high* or *alarm.low* and an actual reading must be requested *volt* for the alarm state to actually be set. The alarm state can be sensed at *alarm/high* and *alarm/low*

**set\_alarm/unset**

*read-write, yes-no*

Status of the power-on-reset (POR) flag.

The POR is set when the DS2450 is first powered up, and will match the alarm state until explicitly cleared. (By writing 0 to it).

The purpose of the POR is to alert the user that the chip is not yet fully configured, especially alarm thresholds and enabling.

**volt.A ... volt.D volt.ALL**

*read-only, floating point*

Voltage read, 16 bit resolution. Range 0 - 5.10V.

Output ( *PIO* ) is specifically disabled.

*ALL* is an aggregate of the voltages. Readings are made separately.

**volt2.A ... volt2.D volt2.ALL**

*read-only, floating point*

Voltage read, 16 bit resolution. Range 0 - 2.55V.

Output ( *PIO* ) is specifically disabled.

*ALL* is an aggregate of the voltages. Readings are made separately.

## STANDARD PROPERTIES

### ALARMS

None.

## DESCRIPTION

### DS2450

The **DS2450 (3)** is a (supposedly) high resolution A/D converter with 4 channels. Actual resolution is reported to be 8 bits. The channels can also function as switches. Voltage sensing (with temperature and current, but sometimes restricted voltage ranges) can also be obtained with the **DS2436**, **DS2438** and **DS276x**

**DESCRIPTION****DS28EC20**The **DS28EC20** (3) is used for storing memory which should be available even after a reset or power off. It's main advantage is for audit trails (i.e. a digital purse). *OWFS* system handles this automatically.**ADDRESSING****DATASHEET**<http://datasheets.maxim-ic.com/en/ds/DS28EC20.pdf>**SEE ALSO****AVAILABILITY**<http://www.owfs.org>**AUTHOR**Christian Magnusson ([mag@mag.cx](mailto:mag@mag.cx))
